

To see a linked list in action, let's follow a sequence of operations starting with an empty list. First, we perform an **insertion at the head** by adding the number **30**, then another insertion at the head with **20**, and finally **10**, resulting in the sequence **10, 20, 30**.

To see what we have, we perform a **traversal**, starting at the head and visiting each node in order until we reach the end. Next, we execute a **deletion at the tail**; the pointer from **20** is updated to null, dropping **30** and leaving us with **10, 20**. We then perform an **insertion at the tail** by adding **40** and **50**, bringing the list to **10, 20, 40, 50**.

Finally, we perform a **deletion by value** for the number **20**. The computer searches the list, finds **20** between **10** and **40**, and reroutes **10**'s pointer to jump directly to **40**. After all these operations, our final linked list stands as **10, 40, 50**.
